React JS

React Props (Properties)

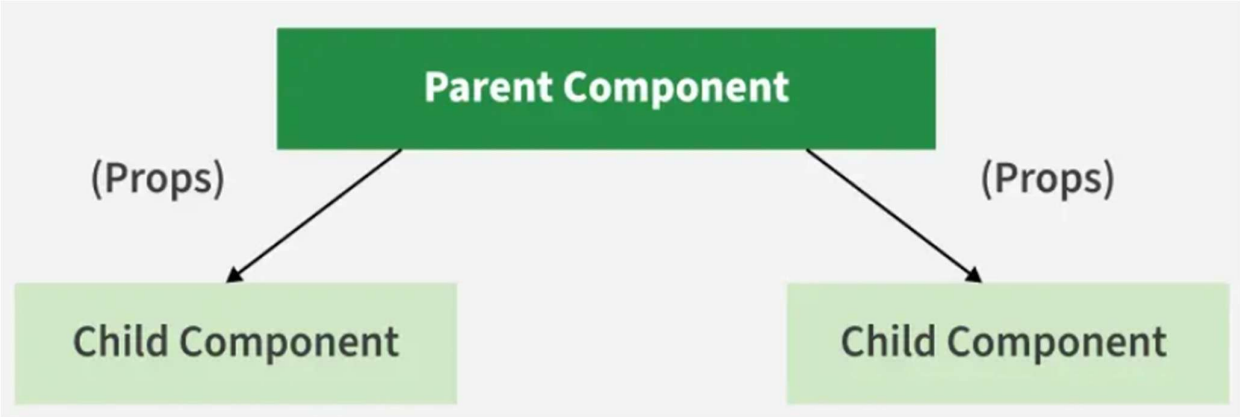
What is Props ?

- Props (short for properties) are a way to **send data** from **one component** to **another.**
- From a **parent component** to **child component**.
- They make components **dynamic** and **reuseable**.
- Props are **read-only** (you cannot change them inside the child component).
- Like passing **ingredients** to a recipe.

Key Components :-

- Props are **immutable** (cannot be changed by the child).
- Used to **reuse components** with different data.
- Passed as **attributes** in JSX.
- Help make components **dynamic and flexible**

Working of Props :-



📌 Example : Passing Props

1. Parent Component –

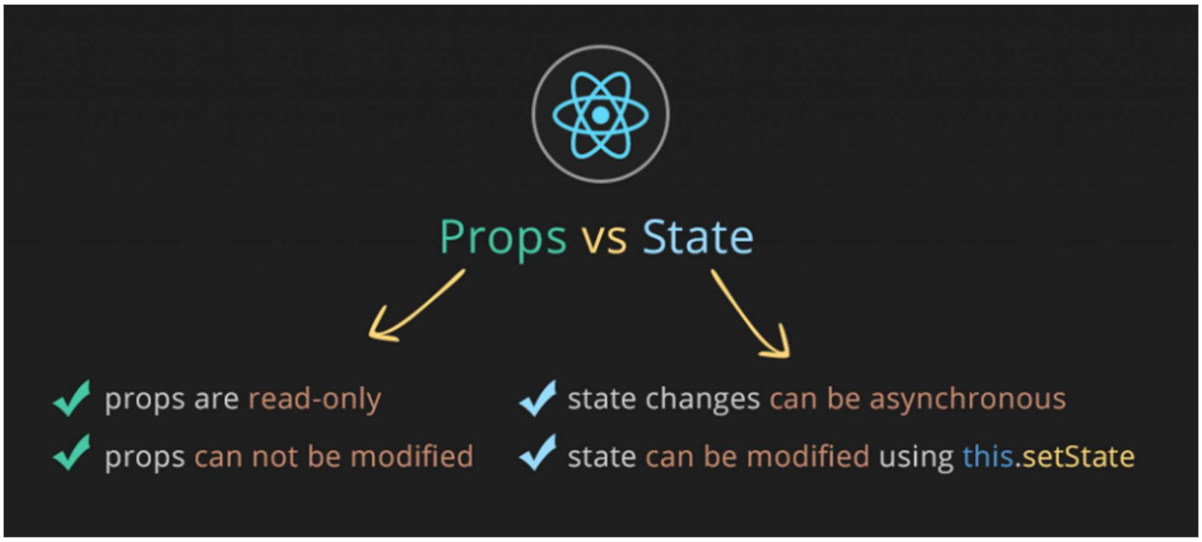
```jsx
function App() {
  return <Student name="Nikhil" course="React JS" />;
}
```

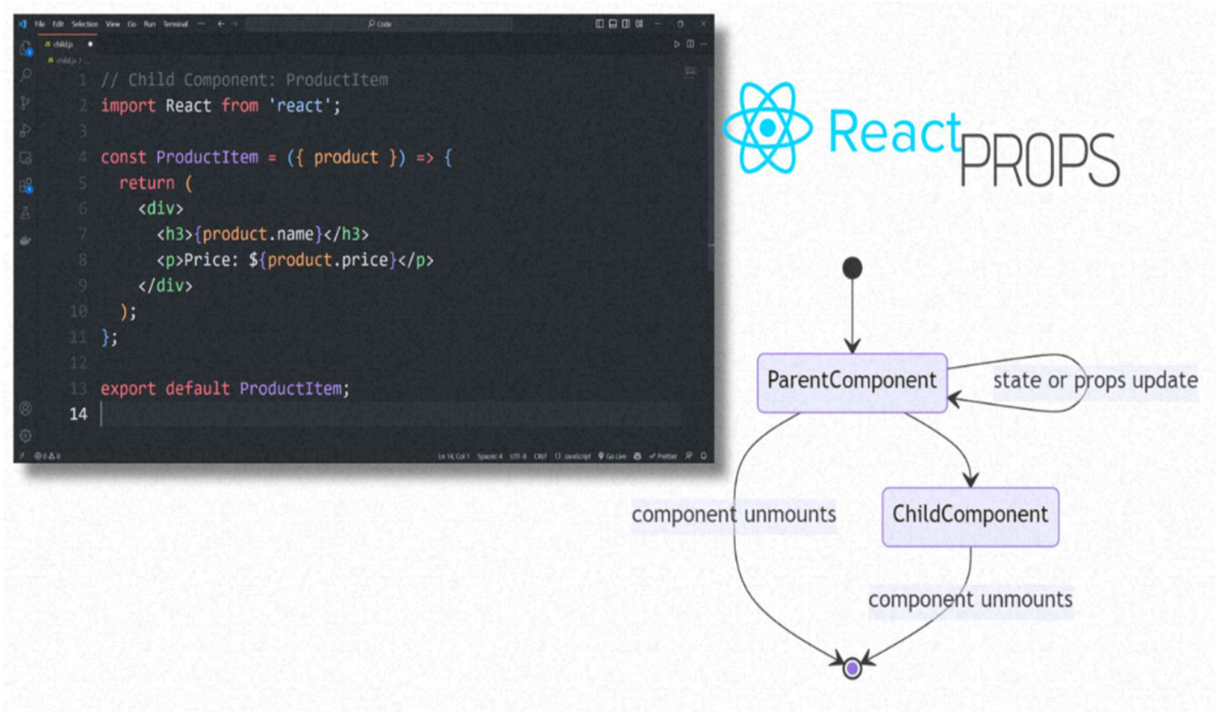
2. Child Component –

```jsx
function Student(props) {
  return (
    <h2>
      Name: {props.name}, Course: {props.course}
    </h2>
  );
}
```

📌 Props vs State –

Props	State
Passed from parent	Managed inside component
Read-only	Mutable
Used for data flow	Used for dynamic data





How to Pass Data Between Components –
